EdDSA and Ed25519  
draft-josefsson-eddsa-ed25519-03

## Abstract

The elliptic curve signature scheme EdDSA and one instance of it called Ed25519 is described. An example implementation and test vectors are provided.

## Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of [BCP 78](#) and [BCP 79](#).

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <http://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on November 13, 2015.

## 1. Introduction

The Edwards-curve Digital Signature Algorithm (EdDSA) is a variant of Schnorr's signature system with Twisted Edwards curves. EdDSA needs to be instantiated with certain parameters and this document describe Ed25519 - an instantiation of EdDSA in a curve over  $GF(2^{255}-19)$ . To facilitate adoption in the Internet community of Ed25519, this document describe the signature scheme in an implementation-oriented way, and we provide sample code and test vectors.

The advantages with EdDSA and Ed25519 include:

1. High-performance on a variety of platforms.
2. Does not require the use of a unique random number for each signature.

3. More resilient to side-channel attacks.
4. Small public keys (32 bytes) and signatures (64 bytes).
5. The formulas are "strongly unified", i.e., they are valid for all points on the curve, with no exceptions. This obviates the need for EdDSA to perform expensive point validation on untrusted public values.
6. Collision resilience, meaning that hash-function collisions do not break this system.

For further background, see the original EdDSA paper [[EDDSA](#)].

TODO: Support SHA-3-512?

## 2. Notation

The following notation is used throughout the document:

$\text{GF}(p)$  finite field with  $p$  elements

$x^y$   $x$  multiplied by itself  $y$  times

$B$  generator of the group or subgroup of interest

$n B$   $B$  added to itself  $n$  times.

$h_i$  the  $i$ 'th bit of  $h$

$a || b$  (bit-)string  $a$  concatenated with (bit-)string  $b$

## 3. Background

EdDSA is defined using an elliptic curve over  $\text{GF}(p)$  of the form

$$-x^2 + y^2 = 1 + d x^2 y^2$$

In general,  $p$  could be a prime power, but it is usually chosen as a prime number. It is required that  $p \equiv 1 \pmod{4}$  (which implies that  $-1$  is a square modulo  $p$ ) and that  $d$  is a non-square modulo  $p$ . For Ed25519, the curve used is equivalent to Curve25519 [[CURVE25519](#)], under a change of coordinates, which means that the difficulty of the discrete logarithm problem is the same as for Curve25519.

Points on this curve form a group under addition,  $(x_3, y_3) = (x_1, y_1) + (x_2, y_2)$ , with the formulas

$$x_3 = \frac{x_1 y_2 + x_2 y_1}{1 + d x_1 x_2 y_1 y_2}, \quad y_3 = \frac{y_1 y_2 + x_1 x_2}{1 - d x_1 x_2 y_1 y_2}$$

The neutral element in the group is (0, 1).

Unlike many other curves used for cryptographic applications, these formulas are "strongly unified": they are valid for all points on the curve, with no exceptions. In particular, the denominators are non-zero for all input points.

There are more efficient formulas, which are still strongly unified, which use homogeneous coordinates to avoid the expensive modulo  $p$  inversions. See [\[Faster-ECC\]](#) and [\[Edwards-revisited\]](#).

#### 4. EdDSA

EdDSA is a digital signature system with several parameters. The generic EdDSA digital signature system is normally not implemented directly, but instead a particular instance of EdDSA (like Ed25519) is implemented. A precise explanation of the generic EdDSA is thus not particularly useful for implementers, but for background and completeness, a succinct description of the generic EdDSA algorithm is given here.

EdDSA has seven parameters:

1. an integer  $b \geq 10$ .
2. a cryptographic hash function  $H$  producing  $2b$ -bit outputs.
3. a prime power  $p$  congruent to 1 modulo 4.
4. a  $(b-1)$ -bit encoding of elements of the finite field  $\text{GF}(p)$ .
5. a non-square element  $d$  of  $\text{GF}(p)$
6. an element  $B \neq (0,1)$  of the set  $E = \{ (x,y) \text{ is a member of } \text{GF}(p) \times \text{GF}(p) \text{ such that } -x^2 + y^2 = 1 + dx^2y^2 \}$ .
7. a prime  $q$ , of size  $b-3$  bits, such that  $qB = (0, 1)$ , i.e.,  $q$  is the order of  $B$  or a multiple thereof.

##### 4.1. Encoding

An element  $(x,y)$  of  $E$  is encoded as a  $b$ -bit string called  $\text{ENC}(x,y)$  which is the  $(b-1)$ -bit encoding of  $y$  concatenated with one bit that is 1 if  $x$  is negative and 0 if  $x$  is not negative. Negative elements

of  $GF(q)$  are those  $x$  which the  $(b-1)$ -bit encoding of  $x$  is lexicographically larger than the  $(b-1)$ -bit encoding of  $-x$ .

#### 4.2. Keys

An EdDSA secret key is a  $b$ -bit string  $k$ . Let the hash  $H(k) = (h_0, h_1, \dots, h_{(2b-1)})$  determine an integer  $a$  which is  $2^{(b-2)}$  plus the sum of  $m = 2^i * h_i$  for all  $i$  equal or larger than 3 and equal to or less than  $b-3$  such that  $m$  is a member of the set  $\{ 2^{(b-2)}, 2^{(b-2)} + 8, \dots, 2^{(b-1)} - 8 \}$ . The EdDSA public key is  $ENC(A) = ENC(aB)$ . The bits  $h_b, \dots, h_{(2b-1)}$  is used below during signing.

#### 4.3. Sign

The signature of a message  $M$  under a secret key  $k$  is the  $2b$ -bit string  $ENC(R) || ENC'(S)$ , where  $ENC'(S)$  is defined as the  $b$ -bit little-endian encoding of  $S$ .  $R$  and  $S$  are derived as follows. First define  $r = H(h_b, \dots, h_{(2b-1)}, M)$  interpreting  $2b$ -bit strings in little-endian form as integers in  $\{0, 1, \dots, 2^{(2b)}-1\}$ . Let  $R=rB$  and  $S=(r+H(ENC(R) || ENC(A) || M)a) \bmod q$ .

#### 4.4. Verify

To verify a signature  $ENC(R) || ENC'(S)$  on a message  $M$  under a public key  $ENC(A)$ , proceed as follows. Parse the inputs so that  $A$  and  $R$  is an element of  $E$ , and  $S$  is a member of the set  $\{0, 1, \dots, l-1\}$ . Compute  $H' = H(ENC(R) || ENC(A) || M)$  and check the group equation  $8SB = 8R + 8H'A$  in  $E$ . Verification is rejected if parsing fails or the group equation does not hold.

### 5. Ed25519

Theoretically, Ed25519 is EdDSA instantiated with  $b=256$ ,  $H$  being SHA-512 [RFC4634],  $p$  is the prime  $2^{255}-19$ , the 255-bit encoding of  $GF(2^{255}-19)$  being the little-endian encoding of  $\{0, 1, \dots, 2^{255}-20\}$ ,  $q$  is the prime  $2^{252} + 0x14def9dea2f79cd65812631a5cf5d3ed$ ,  $d = -121665/121666$  which is a member of  $GF(p)$ , and  $B$  is the unique point  $(x, 4/5)$  in  $E$  for which  $x$  is "positive", which with the encoding used simply means that the least significant bit of  $x$  is 0. The curve  $p$ , prime  $q$ ,  $d$  and  $B$  follows from [I-D.irtf-cfrg-curves].

Written out explicitly,  $B$  is the point (15112221349535400772501151409588531511454012693041857206046113283949847762202, 46316835694926478169428394003475163141307993866256225615783033603165251855960).

### 5.1. Modular arithmetic

For advice on how to implement arithmetic modulo  $p = 2^{255} - 1$  efficiently and securely, see Curve25519 [CURVE25519]. For inversion modulo  $p$ , it is recommended to use the identity  $x^{-1} = x^{(p-2)} \pmod{p}$ .

For point decoding or "decompression", square roots modulo  $p$  are needed. They can be computed using the Tonelli-Shanks algorithm, or the special case for  $p \equiv 5 \pmod{8}$ . To find a square root of  $a$ , first compute the candidate root  $x = a^{((p+3)/8)} \pmod{p}$ . Then there are three cases:

$x^2 = a \pmod{p}$ . Then  $x$  is a square root.

$x^2 = -a \pmod{p}$ . Then  $2^{((p-1)/4)} x$  is a square root.

$a$  is not a square modulo  $p$ .

### 5.2. Encoding

All values are coded as octet strings, and integers are coded using little endian convention. I.e., a 32-octet string  $h[0], \dots, h[31]$  represents the integer  $h[0] + 2^8 h[1] + \dots + 2^{248} h[31]$ .

A curve point  $(x, y)$ , with coordinates in the range  $0 \leq x, y < p$ , is coded as follows. First encode the  $y$ -coordinate as a little-endian string of 32 octets. The most significant bit of the final octet is always zero. To form the encoding of the point, copy the least significant bit of the  $x$ -coordinate to the most significant bit of the final octet.

### 5.3. Decoding

Decoding a point, given as a 32-octet string, is a little more complicated.

1. First interpret the string as an integer in little-endian representation. Bit 255 of this number is the least significant bit of the  $x$ -coordinate, and denote this value  $x_0$ . The  $y$ -coordinate is recovered simply by clearing this bit. If the resulting value is  $\geq p$ , decoding fails.
2. To recover the  $x$  coordinate, the curve equation implies  $x^2 = (y^2 - 1) / (d y^2 + 1) \pmod{p}$ . Since  $d$  is a non-square and  $-1$  is a square, the numerator,  $(d y^2 + 1)$ , is always invertible modulo  $p$ . Let  $u = y^2 - 1$  and  $v = d y^2 + 1$ . To compute the square root of  $(u/v)$ , the first step is to compute the candidate

root  $x = (u/v)^{(p+3)/8}$ . This can be done using the following trick, to use a single modular powering for both the inversion of  $v$  and the square root:

$$x = (u/v)^{(p+3)/8} = u v^3 (u v^7)^{(p-5)/8} \pmod{p}$$

3. Again, there are three cases:

1. If  $v x^2 = u \pmod{p}$ ,  $x$  is a square root.
2. If  $v x^2 = -u \pmod{p}$ , set  $x \leftarrow x 2^{(p-1)/4}$ , which is a square root.
3. Otherwise, no square root exists modulo  $p$ , and decoding fails.
4. Finally, use the  $x_0$  bit to select the right square root. If  $x = 0$ , and  $x_0 = 1$ , decoding fails. Otherwise, if  $x_0 \neq x \bmod 2$ , set  $x \leftarrow p - x$ . Return the decoded point  $(x,y)$ .

#### 5.4. Point addition

For point addition, the following method is recommended. A point  $(x,y)$  is represented in extended homogeneous coordinates  $(X, Y, Z, T)$ , with  $x = X/Z$ ,  $y = Y/Z$ ,  $x y = T/Z$ .

The following formulas for adding two points,  $(x_3,y_3) = (x_1,y_1)+(x_2,y_2)$  are described in [Edwards-revisited], section 3.1. They are strongly unified, i.e., they work for any pair of valid input points.

$$\begin{aligned} A &= (Y_1 - X_1) * (Y_2 - X_2) \\ B &= (Y_1 + X_1) * (Y_2 + X_2) \\ C &= T_1 * 2 * d * T_2 \\ D &= Z_1 * 2 * Z_2 \\ E &= B - A \\ F &= D - C \\ G &= D + C \\ H &= B + A \\ X_3 &= E * F \\ Y_3 &= G * H \\ T_3 &= E * H \\ Z_3 &= F * G \end{aligned}$$

### 5.5. Key Generation

The secret is 32 octets (256 bits, corresponding to  $b$ ) of cryptographically-secure random data. See [RFC4086] for a discussion about randomness.

The 32-byte public key is generated by the following steps.

1. Hash the 32-byte secret using SHA-512, storing the digest in a 64-octet large buffer, denoted  $h$ . Only the lower 32 bytes are used for generating the public key.

2. Prune the buffer. In C terminology:

```
h[0] &= ~0x07;
h[31] &= 0x7F;
h[31] |= 0x40;
```

3. Interpret the buffer as the little-endian integer, forming a secret scalar  $a$ . Perform a known-base-point scalar multiplication  $aB$ .
4. The public key  $A$  is the encoding of the point  $aB$ . First encode the  $y$  coordinate (in the range  $0 \leq y < p$ ) as a little-endian string of 32 octets. The most significant bit of the final octet is always zero. To form the encoding of the point  $aB$ , copy the least significant bit of the  $x$  coordinate to the most significant bit of the final octet. The result is the public key.

### 5.6. Sign

The inputs to the signing procedure is the secret key, a 32-octet string, and a message  $M$  of arbitrary size.

1. Hash the secret key, 32-octets, using SHA-512. Let  $h$  denote the resulting digest. Construct the secret scalar  $a$  from the first half of the digest, and the corresponding public key  $A$ , as described in the previous section. Let  $prefix$  denote the second half of the hash digest,  $h[32], \dots, h[63]$ .
2. Compute  $SHA-512(prefix || M)$ , where  $M$  is the message to be signed. Interpret the 64-octet digest as a little-endian integer  $r$ .
3. Compute the point  $rB$ . For efficiency, do this by first reducing  $r$  modulo  $q$ , the group order of  $B$ . Let the string  $R$  be the encoding of this point.

4. Compute  $\text{SHA512}(R \parallel A \parallel M)$ , and interpret the 64-octet digest as a little-endian integer  $k$ .
5. Compute  $s = (r + k a) \bmod q$ . For efficiency, again reduce  $k$  modulo  $q$  first.
6. Form the signature of the concatenation of  $R$  (32 octets) and the little-endian encoding of  $s$  (32 octets, three most significant bits of the final octets always zero).

#### 5.7. Verify

1. To verify a signature on a message  $M$ , first split the signature into two 32-octet halves. Decode the first half as a point  $R$ , and the second half as an integer  $s$ , in the range  $0 \leq s < q$ . If the decoding fails, the signature is invalid.
2. Compute  $\text{SHA512}(R \parallel A \parallel M)$ , and interpret the 64-octet digest as a little-endian integer  $k$ .
3. Check the group equation  $sB = R + kA$ . It's sufficient, but not required, to instead check  $sB = R + kA$ .

#### 5.8. Python illustration

The rest of this section describes how Ed25519 can be implemented in Python (version 3.2 or later) for illustration. See [appendix A](#) for the complete implementation and [appendix B](#) for a test-driver to run it through some test vectors.

First some preliminaries that will be needed.

```
import hashlib

def sha512(s):
    return hashlib.sha512(s).digest()

# Base field Z_p
p = 2**255 - 19

def modp_inv(x):
    return pow(x, p-2, p)

# Curve constant
d = -121665 * modp_inv(121666) % p

# Group order
q = 2**252 + 27742317777372353535851937790883648493

def sha512_modq(s):
    return int.from_bytes(sha512(s), "little") % q

Then follows functions to perform point operations.
```

# Points are represented as tuples (X, Y, Z, T) of extended coordinates,  
# with  $x = X/Z$ ,  $y = Y/Z$ ,  $x*y = T/Z$

```
def point_add(P, Q):
    A = (P[1]-P[0])*(Q[1]-Q[0]) % p
    B = (P[1]+P[0])*(Q[1]+Q[0]) % p
    C = 2 * P[3] * Q[3] * d % p
    D = 2 * P[2] * Q[2] % p
    E = B-A
    F = D-C
    G = D+C
    H = B+A
    return (E*F, G*H, F*G, E*H)

# Computes Q = s * Q
def point_mul(s, P):
    Q = (0, 1, 1, 0) # Neutral element
    while s > 0:
        # Is there any bit-set predicate?
        if s & 1:
            Q = point_add(Q, P)
        P = point_add(P, P)
        s >>= 1
    return Q

def point_equal(P, Q):
    #  $x_1 / z_1 == x_2 / z_2 \iff x_1 * z_2 == x_2 * z_1$ 
    if (P[0] * Q[2] - Q[0] * P[2]) % p != 0:
        return False
    if (P[1] * Q[2] - Q[1] * P[2]) % p != 0:
        return False
    return True
```

Now follows functions for point compression.

```
# Square root of -1
modp_sqrt_m1 = pow(2, (p-1) // 4, p)

# Compute corresponding x coordinate, with low bit corresponding to sign,
# or return None on failure
def recover_x(y, sign):
    x2 = (y*y-1) * modp_inv(d*y*y+1)
    if x2 == 0:
        if sign:
            return None
        else:
            return 0

    # Compute square root of x2
    x = pow(x2, (p+3) // 8, p)
    if (x*x - x2) % p != 0:
        x = x * modp_sqrt_m1 % p
    if (x*x - x2) % p != 0:
        return None

    if (x & 1) != sign:
        x = p - x
    return x

# Base point
g_y = 4 * modp_inv(5) % p
g_x = recover_x(g_y, 0)
G = (g_x, g_y, 1, g_x * g_y % p)

def point_compress(P):
    zinv = modp_inv(P[2])
    x = P[0] * zinv % p
    y = P[1] * zinv % p
    return int.to_bytes(y | ((x & 1) << 255), 32, "little")

def point_decompress(s):
    if len(s) != 32:
        raise Exception("Invalid input length for decompression")
    y = int.from_bytes(s, "little")
    sign = y >> 255
    y &= (1 << 255) - 1

    x = recover_x(y, sign)
    if x is None:
        return None
    else:
        return (x, y, 1, x*y % p)
```

These are functions for manipulating the secret.

```
def secret_expand(secret):
    if len(secret) != 32:
        raise Exception("Bad size of private key")
    h = sha512(secret)
    a = int.from_bytes(h[:32], "little")
    a &= (1 << 254) - 8
    a |= (1 << 254)
    return (a, h[32:])

def secret_to_public(secret):
    (a, dummy) = secret_expand(secret)
    return point_compress(point_mul(a, G))
```

The signature function works as below.

```
def sign(secret, msg):
    a, prefix = secret_expand(secret)
    A = point_compress(point_mul(a, G))
    r = sha512_modq(prefix + msg)
    R = point_mul(r, G)
    Rs = point_compress(R)
    h = sha512_modq(Rs + A + msg)
    s = (r + h * a) % q
    return Rs + int.to_bytes(s, 32, "little")
```

And finally the verification function.

```
def verify(public, msg, signature):
    if len(public) != 32:
        raise Exception("Bad public-key length")
    if len(signature) != 64:
        Exception("Bad signature length")
    A = point_decompress(public)
    if not A:
        return False
    Rs = signature[:32]
    R = point_decompress(Rs)
    if not R:
        return False
    s = int.from_bytes(signature[32:], "little")
    h = sha512_modq(Rs + public + msg)
    sB = point_mul(s, G)
    hA = point_mul(h, A)
    return point_equal(sB, point_add(R, hA))
```

## 6. Test Vectors for Ed25519

Below is a sequence of octets with test vectors for the the Ed25519 signature algorithm. The octets are hex encoded and whitespace is inserted for readability. Private keys are 64 bytes, public keys 32 bytes, message of arbitrary length, and signatures are 64 bytes. The test vectors are taken from [[ED25519-TEST-VECTORS](#)] (but we removed the public key as a suffix of the secret key, and removed the message from the signature) and [[ED25519-LIBGCRYPT-TEST-VECTORS](#)].

## 7. Acknowledgements

Feedback on this document was received from Werner Koch, Damien Miller, Bob Bradley, and Franck Rondepierre. The test vectors were double checked by Bob Bradley using 3 separate implementations (one

based on TweetNaCl and 2 different implementations based on code from SUPERCOP).

## 8. IANA Considerations

None.

## 9. Security Considerations

### 9.1. Side-channel leaks

For implementations performing signatures, secrecy of the key is fundamental. It is possible to protect against some side-channel attacks by ensuring that the implementation executes exactly the same sequence of instructions and performs exactly the same memory accesses, for any value of the secret key.

To make an implementation side-channel silent in this way, the modulo  $p$  arithmetic must not use any data-dependent branches, e.g., related to carry propagation. Side channel-silent point addition is straight-forward, thanks to the unified formulas.

Scalar multiplication, multiplying a point by an integer, needs some additional effort to implement in a side-channel silent manner. One simple approach is to implement a side-channel silent conditional assignment, and use together with the binary algorithm to examine one bit of the integer at a time.

Note that the example implementation in this document does not attempt to be side-channel silent.
